This discusses the influence of MnO<sub>2</sub> dopant on characteristics volt-ampere (V-I) and volt-time (V-t) in varistor metal oxide with principal materials of ZnO. The composition concentration of MnO<sub>2</sub> is varied from 0.5 % mol, 1% mol, 1.5 % mol, 2 % mol, and 5 % mol. Ceramics varistor zno and zno dopan with MnO<sub>2</sub> have done. Making process varistor this pass 3 stages that is preparation with mix powder ZnO with powder MnO<sub>2</sub>, printing process with dry pressing method and the last process is sintering varistor disk in 1300 °C. After that, the characteristics of volt-ampere (V-I) and characteristics character volt-time (V-t).

From V-I characteristics constants non-linear ( $\beta$ ) and varistor resistance are obtained. Adding 0,5 % and 1 % mol MnO<sub>2</sub> can increase non-linear constant varistor with  $\beta$  smaller is compared to that of ZnO varistor pure. It also increase varistor resistances. While for the others decrease varistor resistances.

The result from characteristics measurement V-t is got response curve varistor and characteristics curve V-t varistor. Varistor ZnO pure and ZnO-MnO<sub>2</sub> has response curve varistor present under impulse voltage curve. It's has characteristics curve V-t lower compared with characteristics curve V-t impulse voltage. so that can be said varistor work. Varistor ZnO-MnO<sub>2</sub> has characteristics curve V-t lower than varistor ZnO. And ZnMn 2 % has lowers characteristics curve between varistor ZnO-MnO<sub>2</sub> the other.

Keyword: varistor, ZnO-MnO<sub>2</sub>, characteristics volt-ampere (V-I), characteristics volt-waktu (V-t), non-linearity varistor
